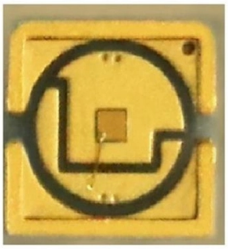
From Core Switch to Access Layer



Overview

This tutorial provides an overview of the access, distribution, and core layers and explains two-tier and three-tier campus LAN designs.

Key Takeaways

Data flows from the core switch through the distribution layer to access switches, which connect end devices to the network.

Core Layer

The core switch forms the backbone of the network, providing high-speed, low-latency connectivity between distribution switches and other core devices. It handles massive volumes of traffic and ensures reliable, fast transport across the network. Core switches are optimized for scalability, fault tolerance, and high throughput, often supporting advanced features like in-service software upgrades (ISSU) to maintain uptime during updates.

Distribution Layer

The distribution layer acts as an intermediary between the core and access layers. Distribution switches aggregate traffic from multiple access switches, perform inter-VLAN routing, enforce policies such as Quality of Service (QoS) and Access Control Lists (ACLs), and reduce broadcast traffic. They selectively route and switch data packets to the correct access devices, preventing congestion and ensuring efficient traffic flow.

Access Layer

The access layer is where end-user devices connect to the network. Access switches, often Layer 2 or Layer 3 devices, provide connectivity to PCs, IP phones, Wi-Fi access points, and other endpoints. They are designed for high port density and support speeds typically ranging from 10/100/1000 Mbps, with some supporting multi-gigabit uplinks.

Access switches receive routed and switched traffic from distribution switches and forward it to the connected devices, ensuring proper delivery without back-transmission to the core.

Data Flow Summary

Core switch: Aggregates and forwards large volumes of traffic across the network backbone. Distribution switch: Receives traffic from the core, applies routing and policy enforcement, and directs packets to the appropriate access switches. Access switch: Delivers traffic to end devices and subnets, providing the final connection point for users and devices.

This hierarchical model ensures scalability, manageability, and performance, allowing network architects to isolate failures, apply consistent security policies, and optimize traffic flow from the core to the edge of the network.
